

Research Priorities in Marine Geology and Geophysics:

What drives the recurrence of large earthquakes?

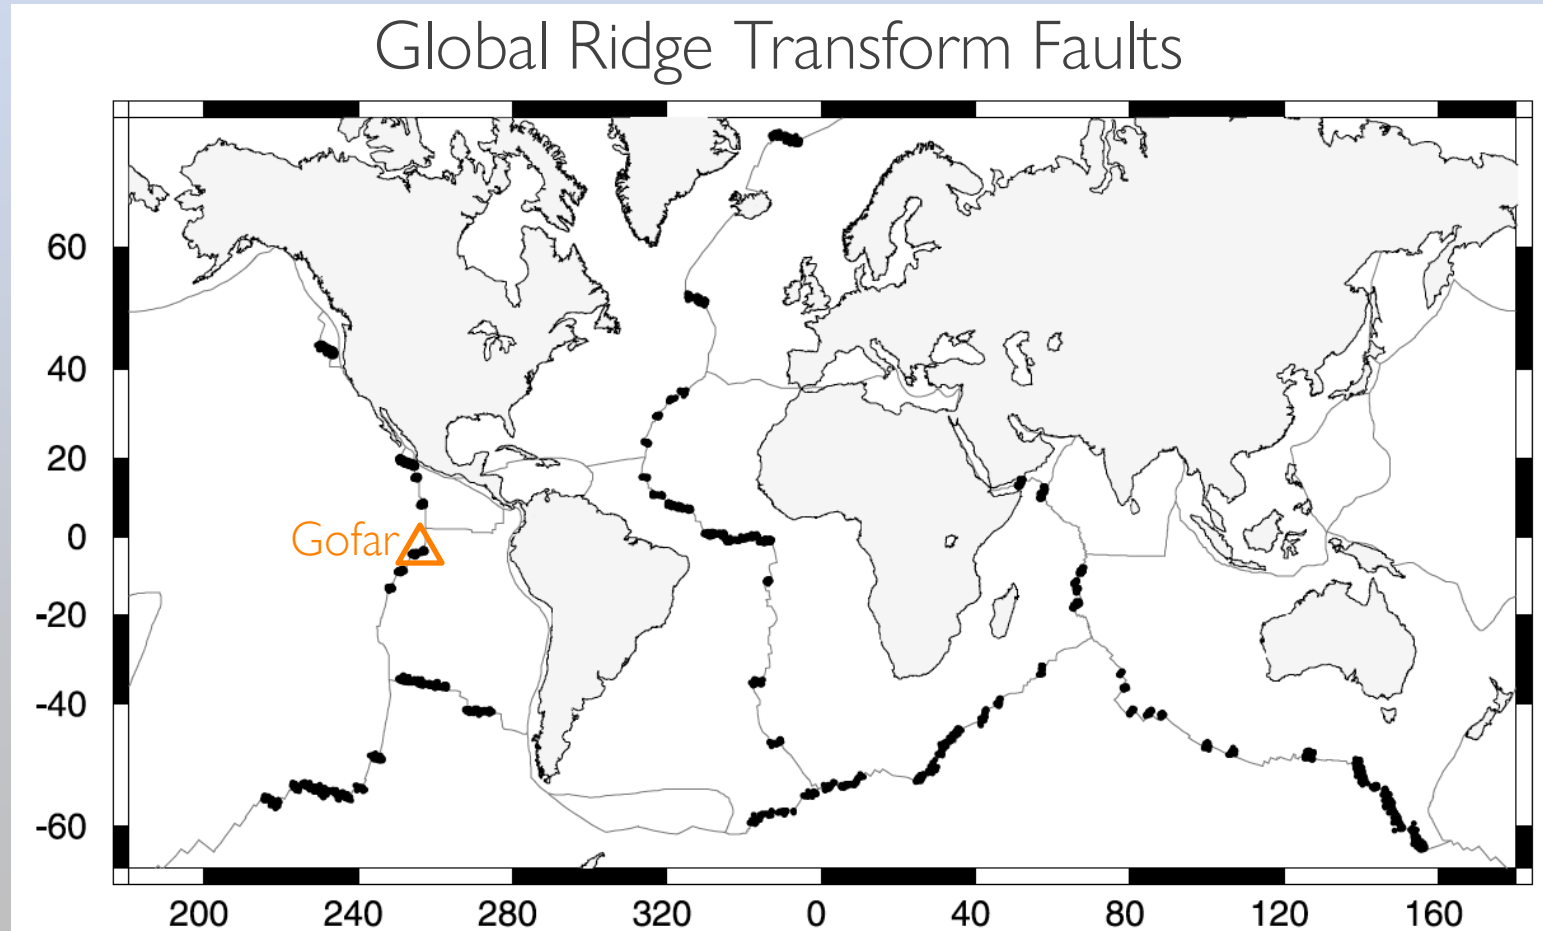

A multidisciplinary study of oceanic transform faults

Jessica M. Warren, University of Delaware

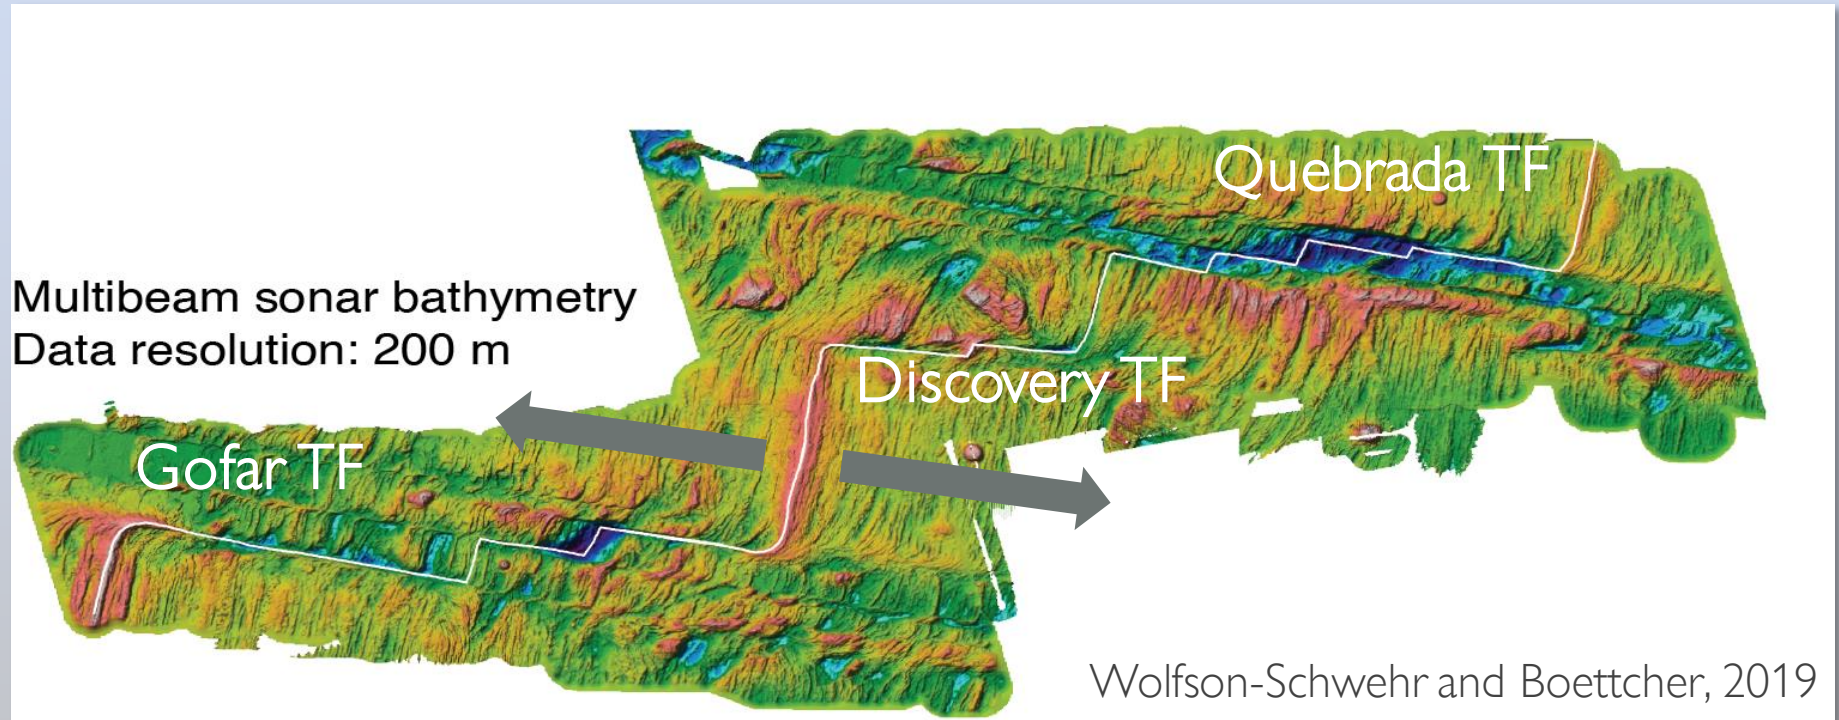

This presentation is based upon work supported by the U.S. National Science Foundation

The seafloor has >16,000 km of transform faults.

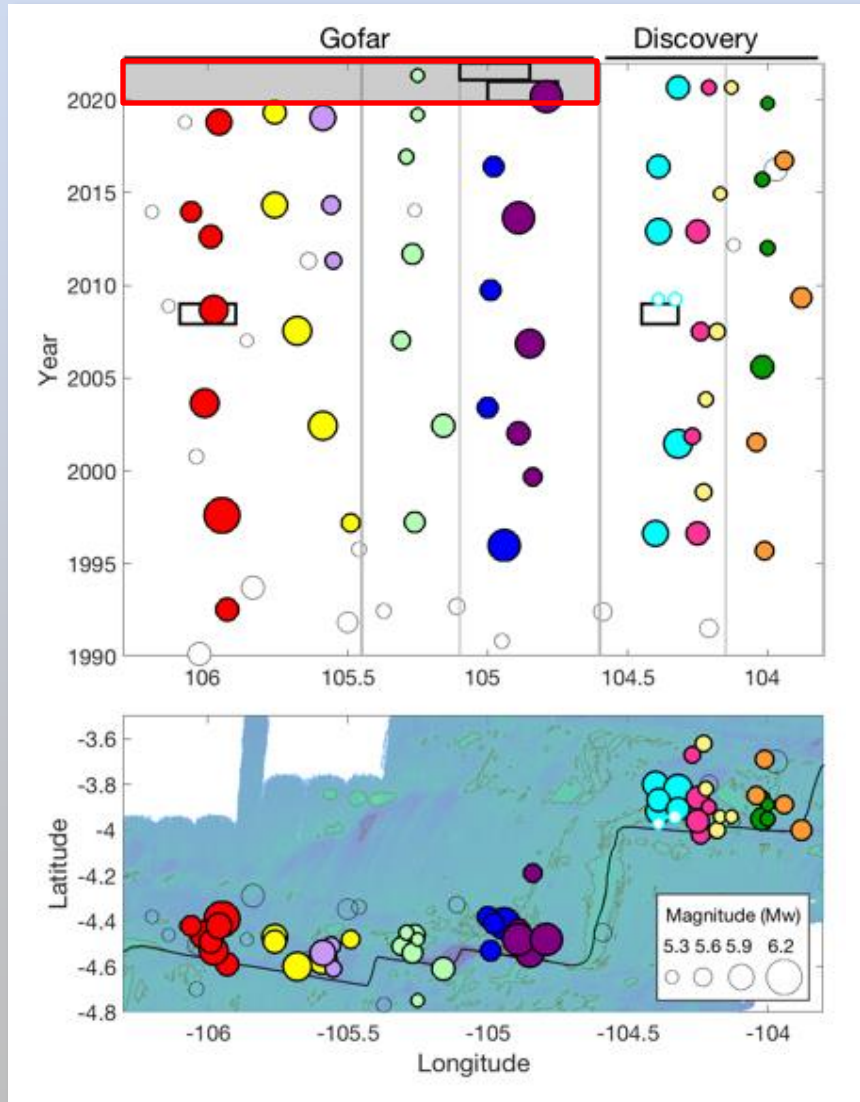

Boettcher & Jordan, JGR, 2004

Gofar-Discovery-Quebrada Transform Faults

- Slip rates of 12 cm per year → 4x faster than the San Andreas Fault!
- Gofar is the most studied oceanic transform fault for seismicity.

These faults allow us to explore the mechanisms leading to earthquakes

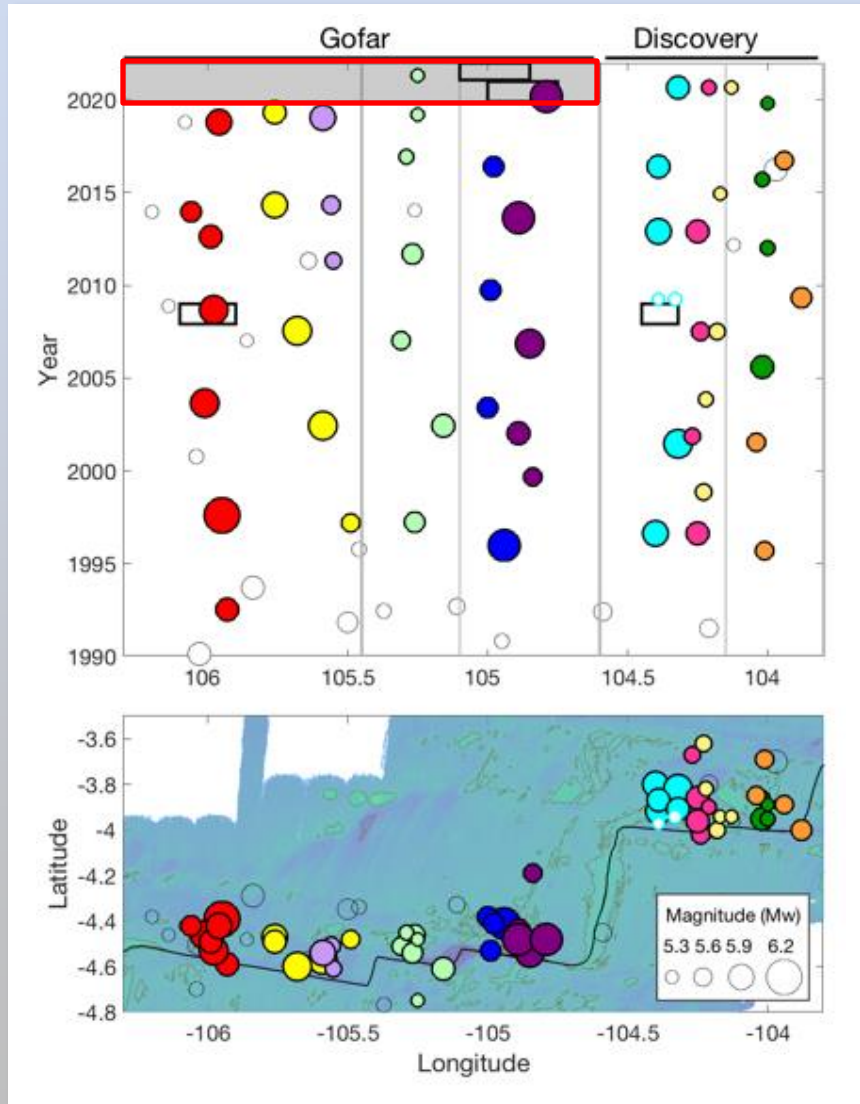

Key observations:

- Repeating earthquakes on seismically active sections.
- No earthquakes in barrier zones, which limit large ruptures.
- The repeating earthquakes are some of the most predictable earthquakes on Earth.

Seismometers deployed December 2019

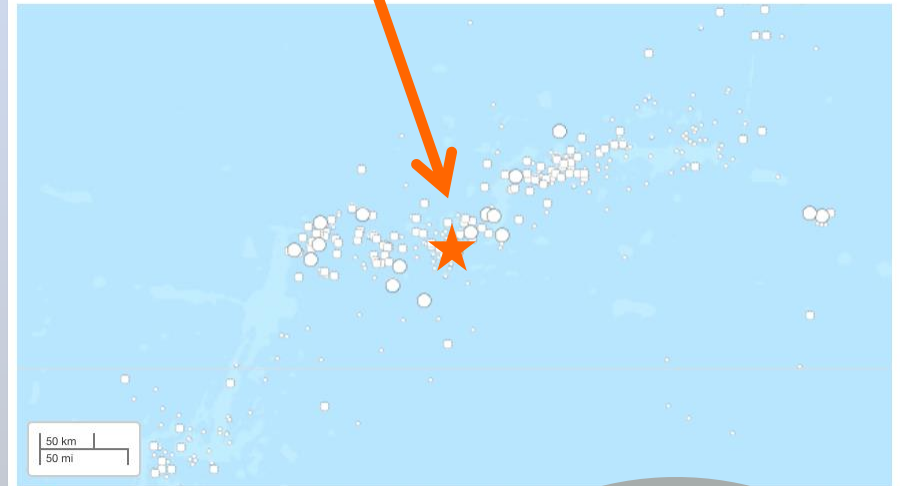

M6.1 earthquake in March 2020

Boettcher et al., in prep.

M 6.1 - Central East Pacific Rise

2020-03-22 22:38:04 (UTC) | 4.674°S 104.912°W | 10.0 km depth

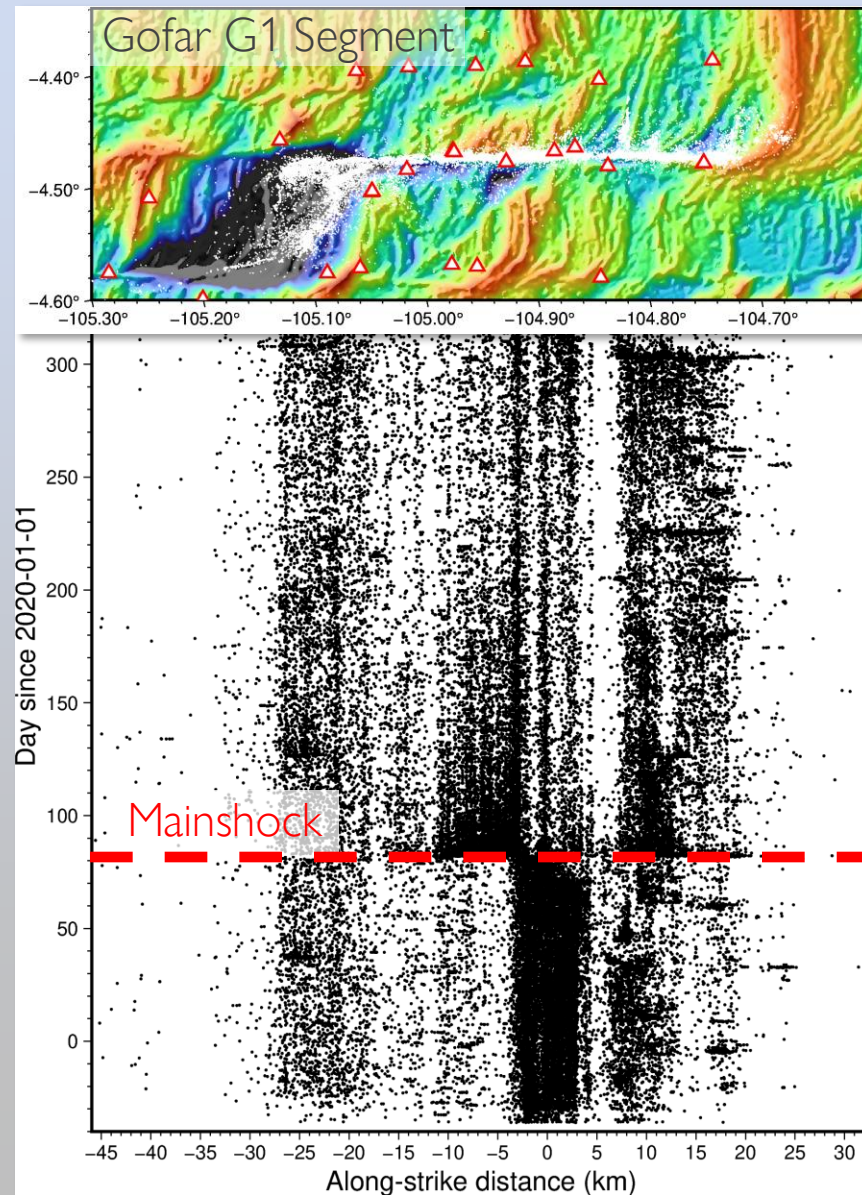

Our proposed deployment... covers a significant portion of the expected PDF of each upcoming earthquake.

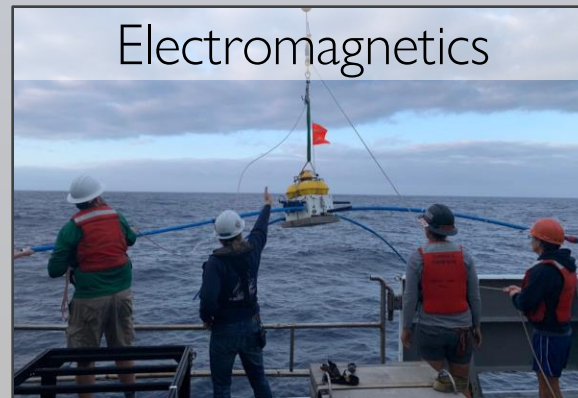

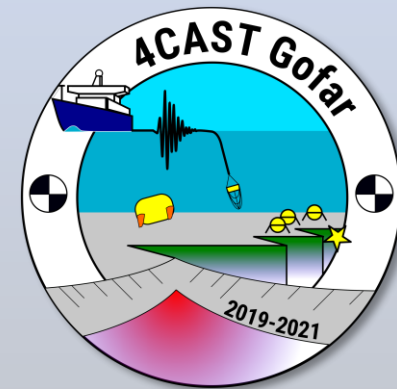

Margaret Boettcher

Microseismicity changes following a large earthquake

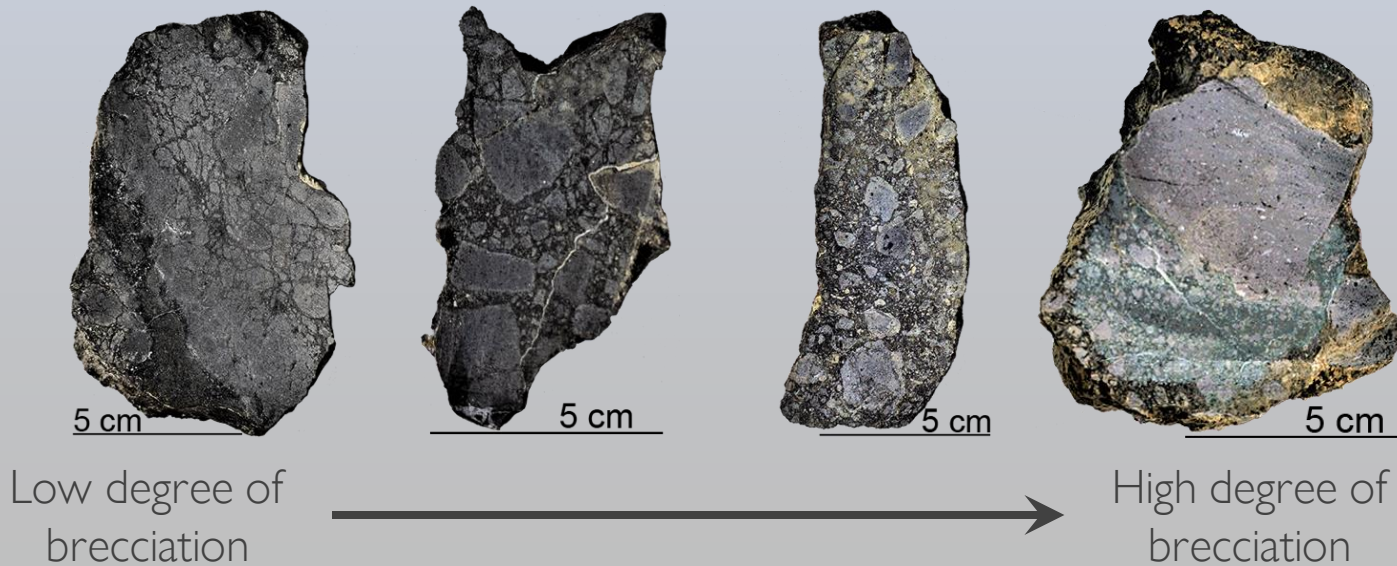

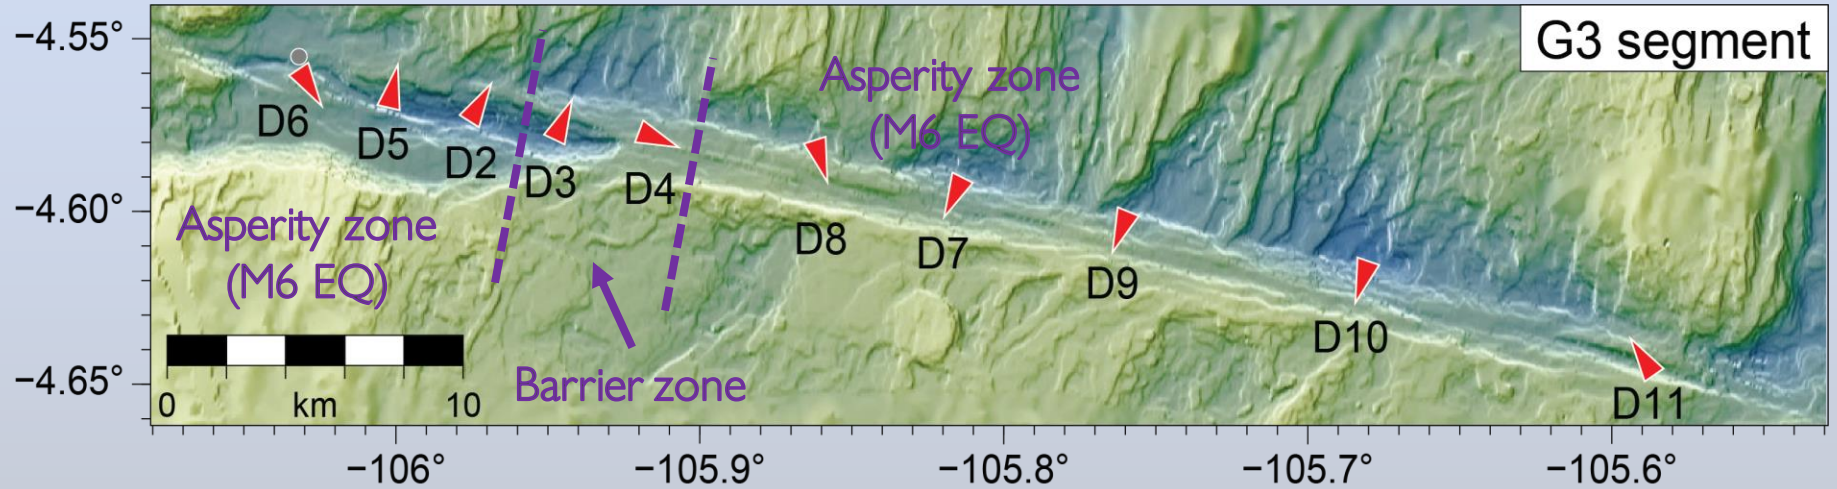

2019-2022 Gofar Transform Fault Experiment

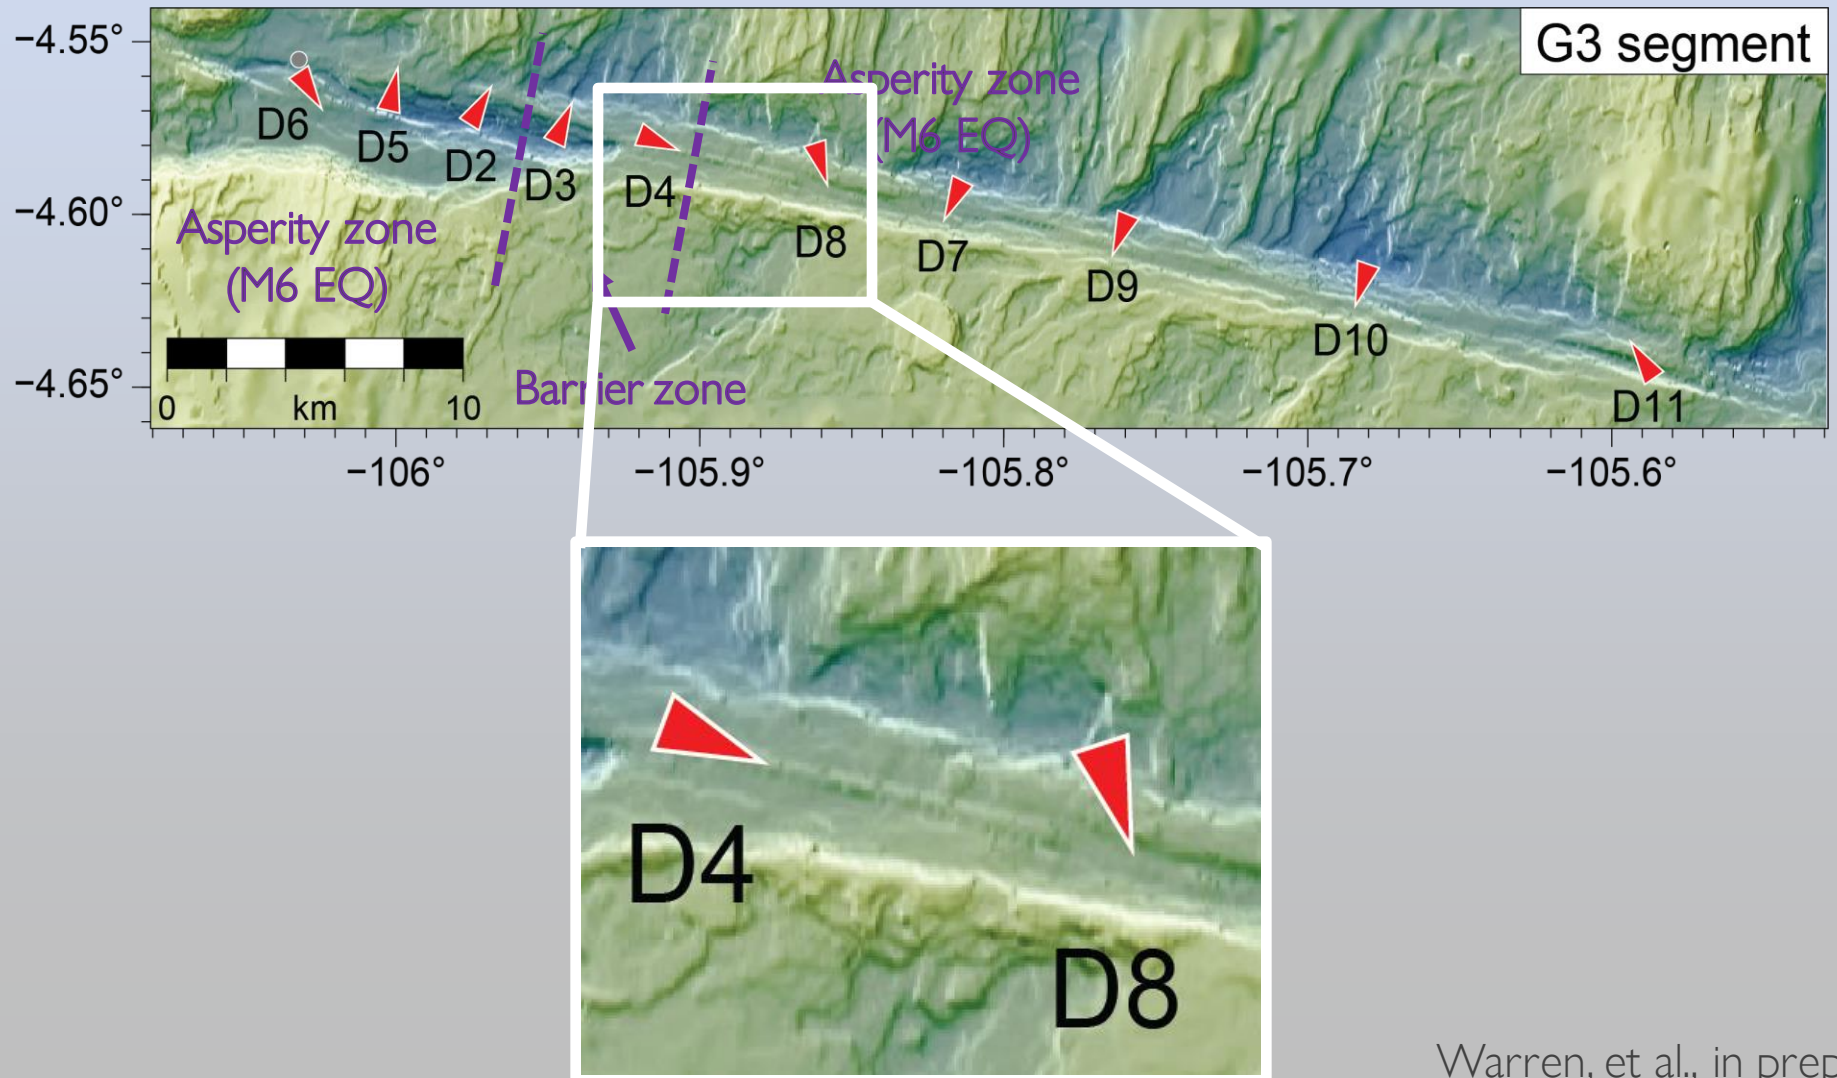

- To identify the role of fluid flow for fault structure.
- To investigate why barrier zones limit large earthquakes.

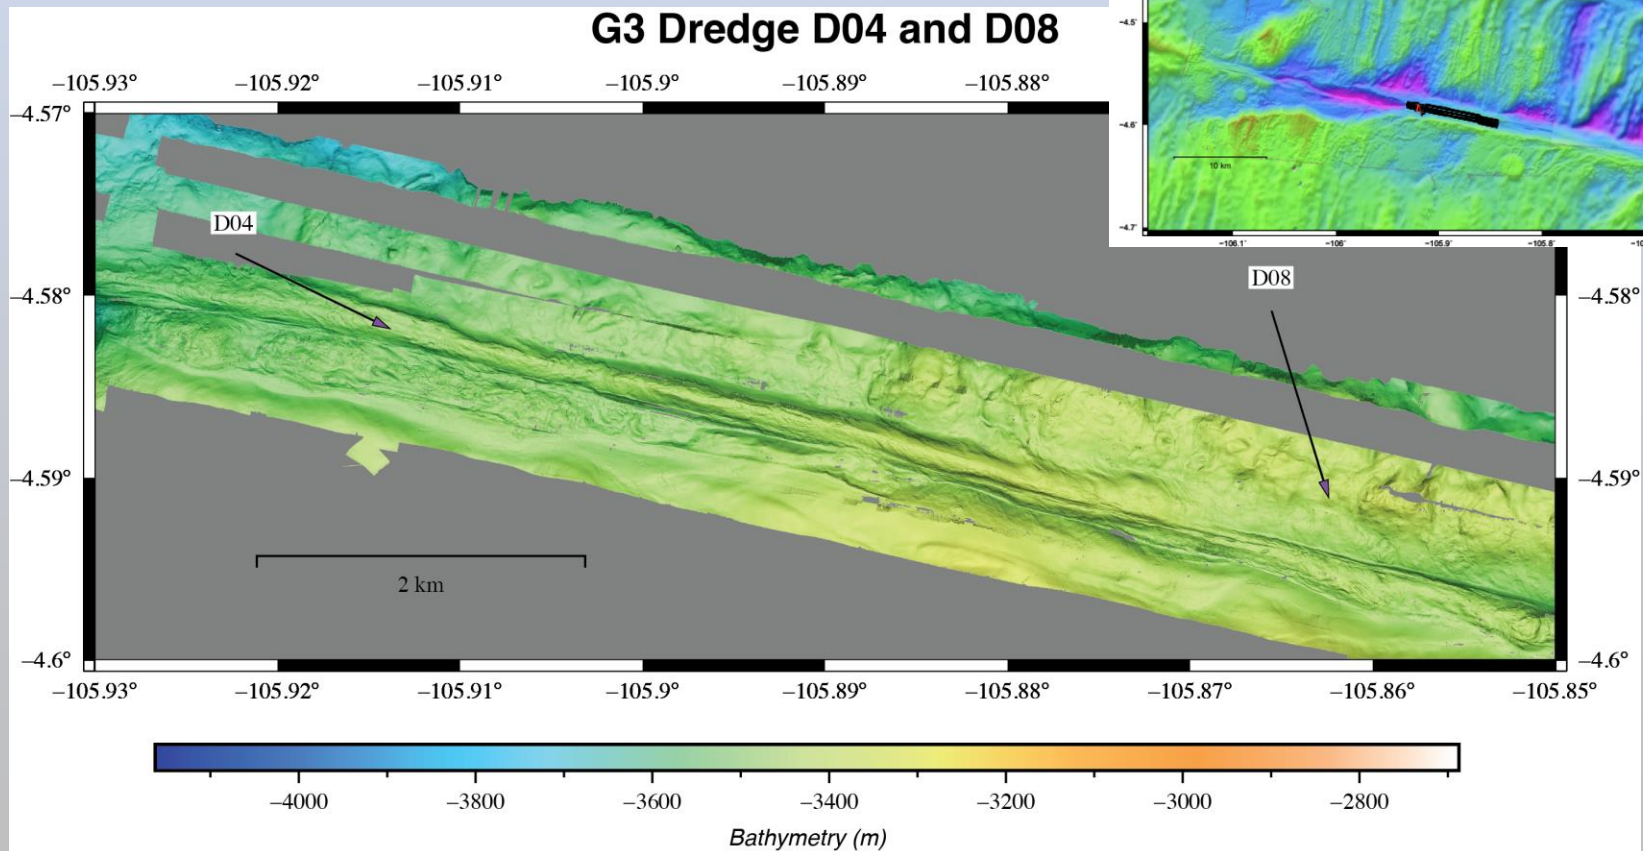

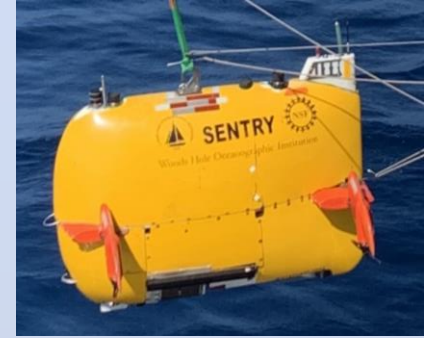

Dredging campaign to recover fault-zone samples

Shipboard bathymetry allows us to
guess at the fault location

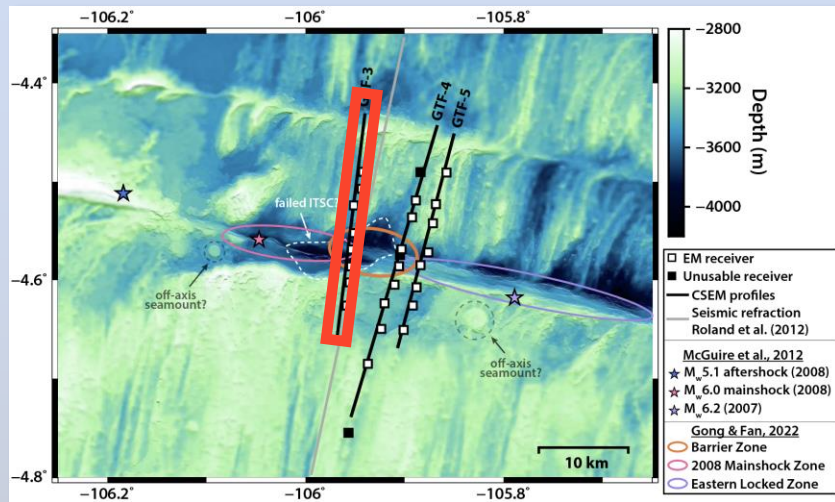

AUV Sentry high-resolution microbathymetry provides detailed view of fault structure

Koenig, Roland, et al., in prep

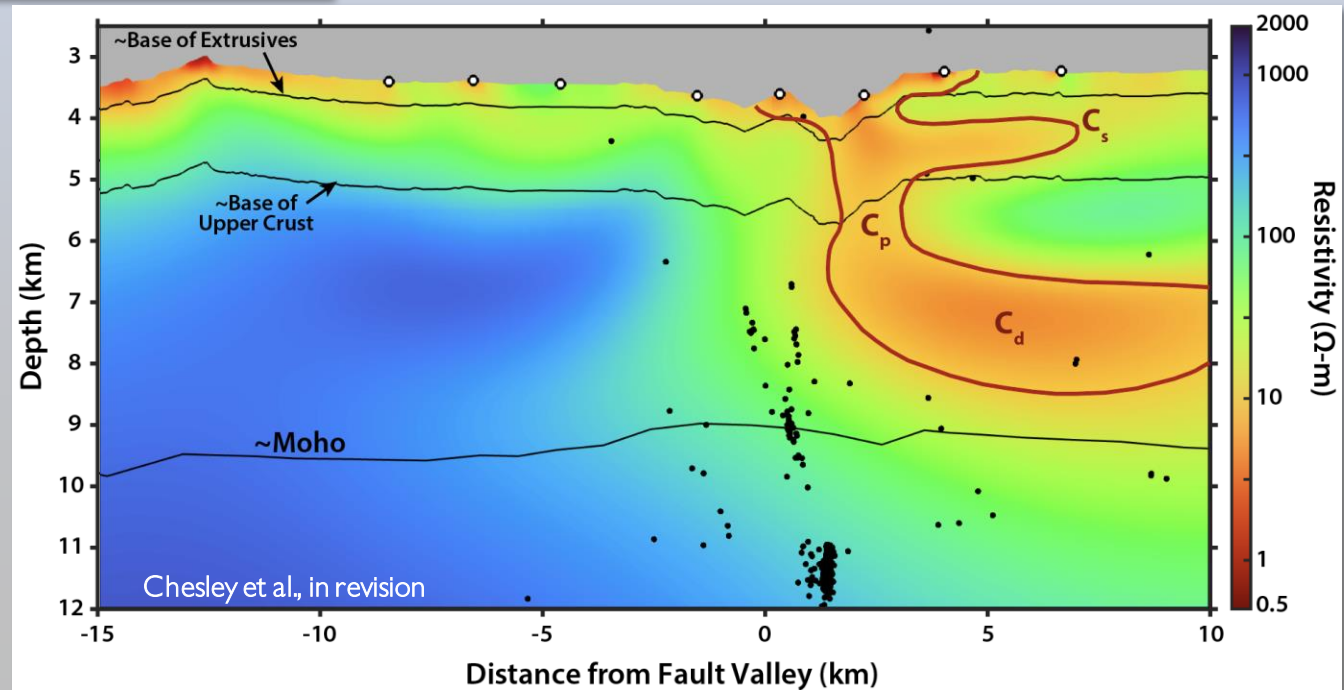

Electrical resistivity reveals conductive anomalies

Anomalies are on the south (younger crust) side of the fault:

- Deep (C_d)
- Shallow (C_s)
- Pipe-like (C_p)

→ Possible flow of brines in the fault.

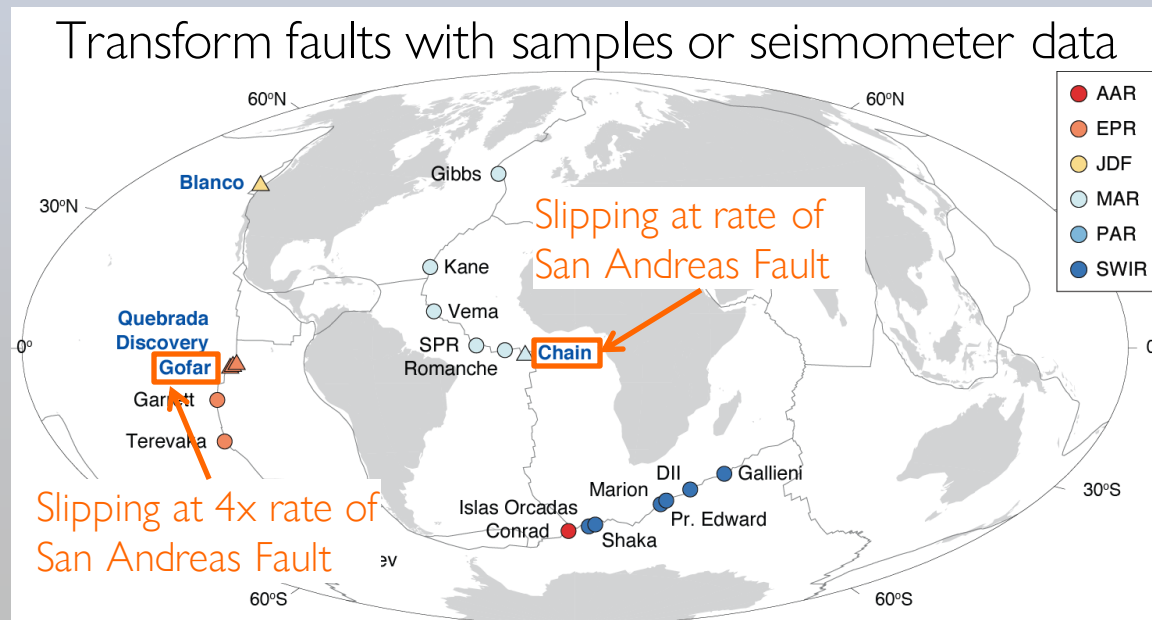

Seismicity from Gong and Fan 2022 are relocated 2008 EQs w/in 250 m of profile

Chesley et al., in revision

What drives the recurrence of large earthquakes?

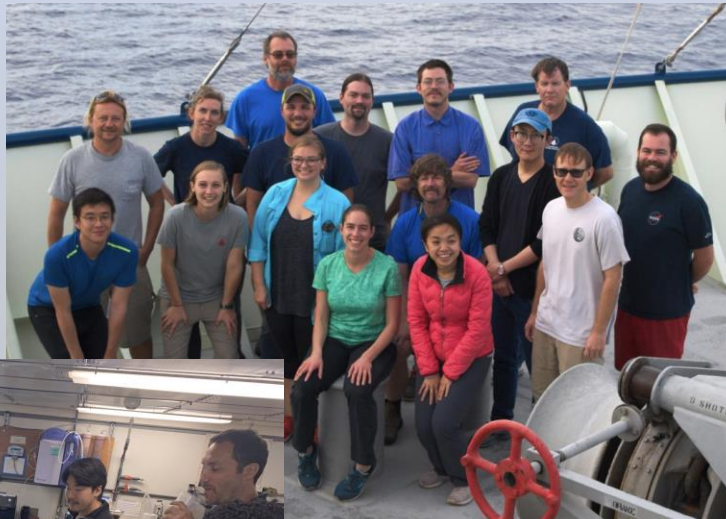

To link fluid flow to earthquakes and creep, we need to:

- Sample the rupturing part of the fault.
- Conduct ROV/HOV transects of the fault.
- Study additional faults, particularly faults slipping at similar rates to continental faults.

Work force training in multidisciplinary science

- Gofar project involved ~20 undergraduates, grad students, and postdocs.
- They now have careers in academia, industry, government.

Boettcher et al., 2023

Research infrastructure: Dredging

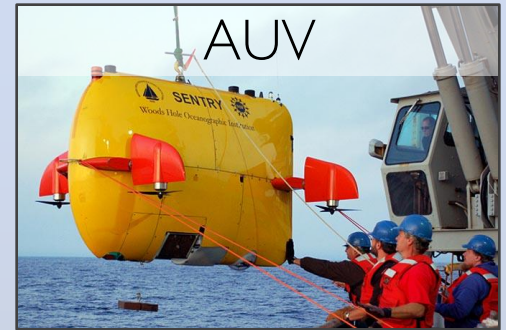

- Need systems capable of handling large tensions.
- Requires synthetic lines to replace steel wires.
- A-frames and winches upgraded for handling high tensions.
- These upgrades also needed for coring & mooring deployments.
- Use of these systems will increase with IODP going offline.

Research infrastructure: Facilities

Deep submergence (HOV/ROV/AUV):

- State-of-the-art
- Limited availability – upgrade other equipment to take pressure off HOV/ROV/AUV

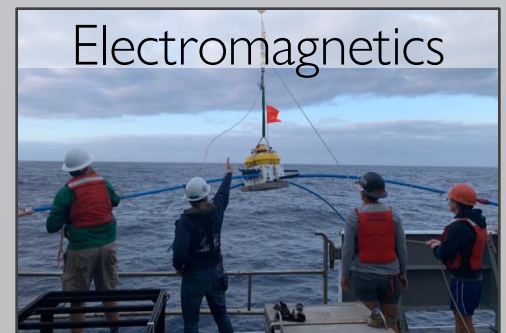

Ocean bottom seismometers

- High demand
- Aging instrument pool

Marine Electromagnetism

- Facility needed

Seafloor geodesy

- Further development needed

Research infrastructure: Ships

Global Class Vessels

- Huge demand for these ships.
- Need increased capabilities.
- Refits would improve some aspects (e.g., synthetic wires).
- Long-term planning needed for the US to remain a global leader in marine research.

What drives the recurrence of large earthquakes?

To link fluid flow to earthquakes and creep, we need to:

- Sample the rupturing part of the fault.
- Conduct ROV/HOV transects of the fault.
- Study additional faults, particularly faults slipping at similar rates to continental faults.
