Pathways to Optimized Use of Technology

Its not about the technology –

The use case (question) & user are key

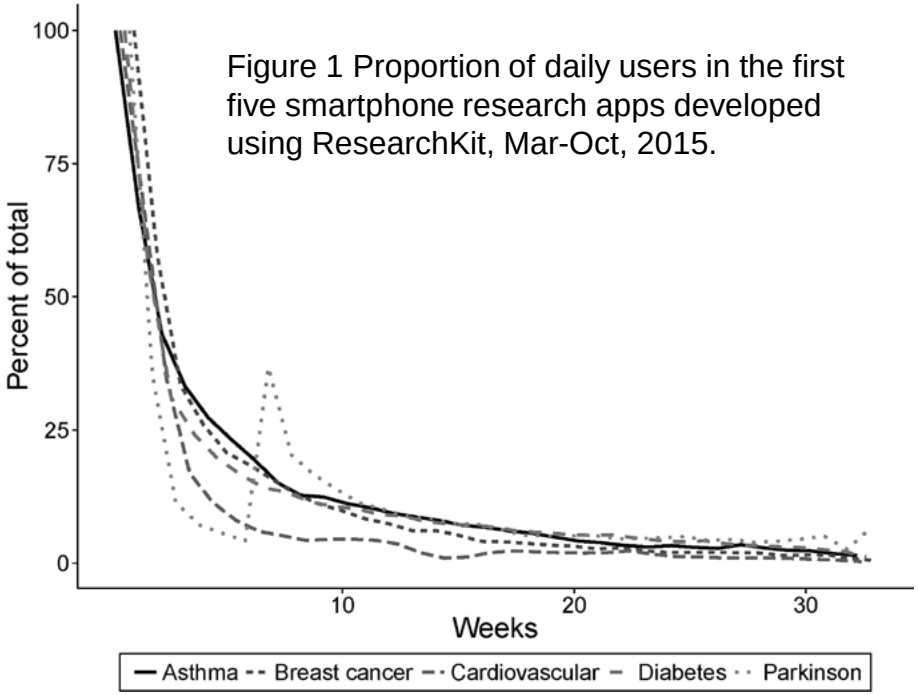

Figure 1 Proportion of daily users in the first five smartphone research apps developed using ResearchKit, Mar-Oct, 2015.

Dorsey et al. Academic Medicine, 2017;92(2):157-60.

- If you have a smartphone, everything is an app…

Reactions to a Remote-Controlled Video-Communication Robot in Seniors' Homes: Feasibility and Acceptance

VGO

Table 2. Example Participant Feedback
• "It was nice that my daughter didn't always have to come over."
• "Gave me a sense of safety."
• "It was like another person. I was sad to see it go."
• "It would be good for checking on a sedentary person."
• "Not sure what the purpose is supposed to be."
• "It was too complicated…overwhelming."[a]
[a]Participant who progressed to mild cognitive impairment.

Table 3. Example Remote Collateral Feedback
• "Everyone that's older should have one."
• "It's a great tool that would give the family peace of mind."
• "When I felt like checking up on him I could just log on."
• "(It would be useful) to alert health care providers of anything dangerous like elevated heart rate."

Ambient Independence Measures for Guiding Care Transitions

NIA/NIBIB - AG042191

AIMS Summary Aims

- Based *on user-centered design*, develop a pervasive computing system tuned to identify *trends* in AIMs data predictive of relevant (for transition decisions) functional and health change. The platform will present AIMs data on a regular or as-needed basis to care teams.
- Assess the efficacy of using AIMs metrics and the data-based tool in senior community settings to improve care transition decisions via a RCT (usual care vs. AIMS informed care).

7 sites, 26 decision makers, 95 residents; 3 years follow-up

AIMS for Guiding Care Transitions - Results

Despite user-centered design and high enthusiasm at the start of the study, and 'booster intervention' at midpoint, poor use of the dashboard over time.

Reasons (Exit interviews):

- **Not sure what to do with trend data:**

"*There is a fine line between monitoring someone's independent lives and knowing when to interfere for safety reasons… It is hard to know when to involve a care team without being too Orwellian. I would likely wait a month and then have a bit more data to take to a team meeting to assess the subtle changes collectively*."

- **Not part of Institutional System (Optional / Voluntary Use)**
  - Separate system from their facility's system
  - Not clear who should take the lead on the data
  - Just trying to keep the toilets working

Testing Acceptance for Interventions:
The "Social Engagement Study" (H. Dodge, PI)
RCT Pilot to Test Increasing Social Interaction in MCI Using Home-based Technologies

- 6 week RCT of daily 30 min video chats using automated Internet connected personal computers with a webcam vs. weekly brief phone interview
- N = 86; 80.5 ± 7 yrs; MCI & Normal Cognition
- **89% of all possible sessions completed; Exceptional adherence – *no drop-out***
- MCI participants > proportion of words (2985 vs. 2423) per total number of words during the conversation sessions (controlling for age, gender, interviewer and time of assessment; p=0.03).

AIMS for Guiding Care Transitions

Seven Retirement Communities / 26 Decision Makers

Directors, nurses, social workers, resident care coordinators); ages 21-66 (mean = 40 yrs); employed at facility mean = 10 yrs; education- high school to master's (68% ≥ college)

Care staff focus groups and surveys addressing:

- If the data showed information that was meaningful to them;
- If they believed residents would be willing to have that type of data shared with the transition teams;
- If anybody, it might be helpful to share the data with;
- If there were other types of data they would like to see;
- How, and how often, data should be presented for their decision making.

Focus groups held in two waves:

1st round - three sites; 2nd round, initial feedback incorporated into the online dashboard for additional input. Dashboard designer present at all focus groups

Review Article

Use of Mobile Devices to Measure Outcomes in Clinical Research, 2010–2016: A Systematic Literature Review

Brian Perry[a, b] Will Herrington[c] Jennifer C. Goldsack[b, d]
Cheryl A. Grandinetti[e] Kaveeta P. Vasisht[e] Martin J. Landray[c]
Lauren Bataille[f] Robert A. DiCicco[g] Corey Bradley[h] Ashish Narayan[i]
Elektra J. Papadopoulos[e] Nirav Sheth[j] Ken Skodacek[k] Komathi Stem[l]
Theresa V. Strong[m] Marc K. Walton[n] Amy Corneli[a, b]

ence monitors, and (5) location monitors; inertial sensors/accelerometers were most common (reported in 86% of the publications). Among the variety of mobile outcomes, various assessments of physical activity were most common (reported in 74% of the publications). Other mobile outcomes included assessments of sleep, mobility, and pill adherence, as well as biomarkers assessed using a mobile device, including cardiac measures, glucose, gastric reflux, respiratory measures, and intensity of head-related injury. ***Conclusion:*** Mobile devices are being widely used in clinical research to assess outcomes, although their use in interventional research to assess therapeutic effectiveness is limited. For mobile devices to be used more frequently in pivotal interventional research – such as trials informing regulatory decision-making – more focus should be placed on: (1) consolidating the evidence supporting the clinical meaningfulness of specific mobile outcomes, and (2) standardizing the use of mobile devices in clinical research to measure specific mobile outcomes (e.g., data capture frequencies, placement of device). To that aim, this manuscript offers a broad overview of the various mobile outcome assessments currently used in observational and interventional research, and categorizes and consolidates this information for researchers interested in using mobile devices to assess outcomes in interventional research.

Summary of Evidence & Gaps

- The technologies used are wide-ranging (passive sensors, wearables, apps, integrated multi-domain systems...), and used in many types of assessments and interventions;
- Overall, few studies relative to other research areas: this is still a small field;
- Standardization gaps: variability in the devices or technologies used (hardware/software), and limits in specification of the systems deployed and the analytic algorithms applied;
- More research needed on usability;
- Various benefits may be reported but mainly based on low-quality studies (small sample sizes, short study periods, biased designs, non-diverse populations);
- Barriers to deployment of technologies in care are prevalent (ease of use, research expertise, costs, *and lack of evidence of efficacy or effectiveness*).
