

Emerging Science and Technology to Address Naval Undersea Medicine Needs:

: Lessons Learned from Analog Contexts and Lunar Mission Planning

Robert Sanders, MD, FACEP, FUHM
Flight Surgeon, Program Medical Officer,
EVA & Human Surface Mobility Program,
National Aeronautics and Space Administration (NASA)

NASA & Submarine Medicine

- **Background:**
 - Similarities and challenges of lunar mission planning parallel that of submarine operation
 - Looking to Industry for initial solutions
 - Some can leverage terrestrial analogs/models
 - Others must be solved by NASA directly

Lunar EVA Requirements

- **Artemis Mission: Astronaut into the field**

- Return to the lunar surface for science and exploration
- Initially lander-based operations (Artemis 3+)
- Pressurized rover ops (Artemis 7+)
- **Rapid deployment EVA (spacewalks)**
 - ISS model not efficient enough
 - Solution space:
 - Habitation & suit pressure
 - Gas mixes

EVA: extravehicular activity;

Conditions for DCS (ISS operations)

- ❖ Decrease in Pressure
- ❖ Change in Phase State
- ❖ Supersaturation must be present
 - Tissue $pN_2 > \text{Ambient Pressure}$

ISS operational mitigation: oxygen prebreathe
Prebreathe time based on risk acceptance

Risk Definition

– DCS risk (human health)

- $\leq 15\%$ Type I DCS and Cutis Marmorata with 95% confidence interval
- $\leq 20\%$ grade IV VGE (95% confidence interval)
- NO Type II DCS

– Lesson learned:

- If risk acceptance is high enough, adverse medical outcomes may not be “contingencies” or failures, and *must* be planned for:
- i.e. DCS is a statistical likelihood and not a failure

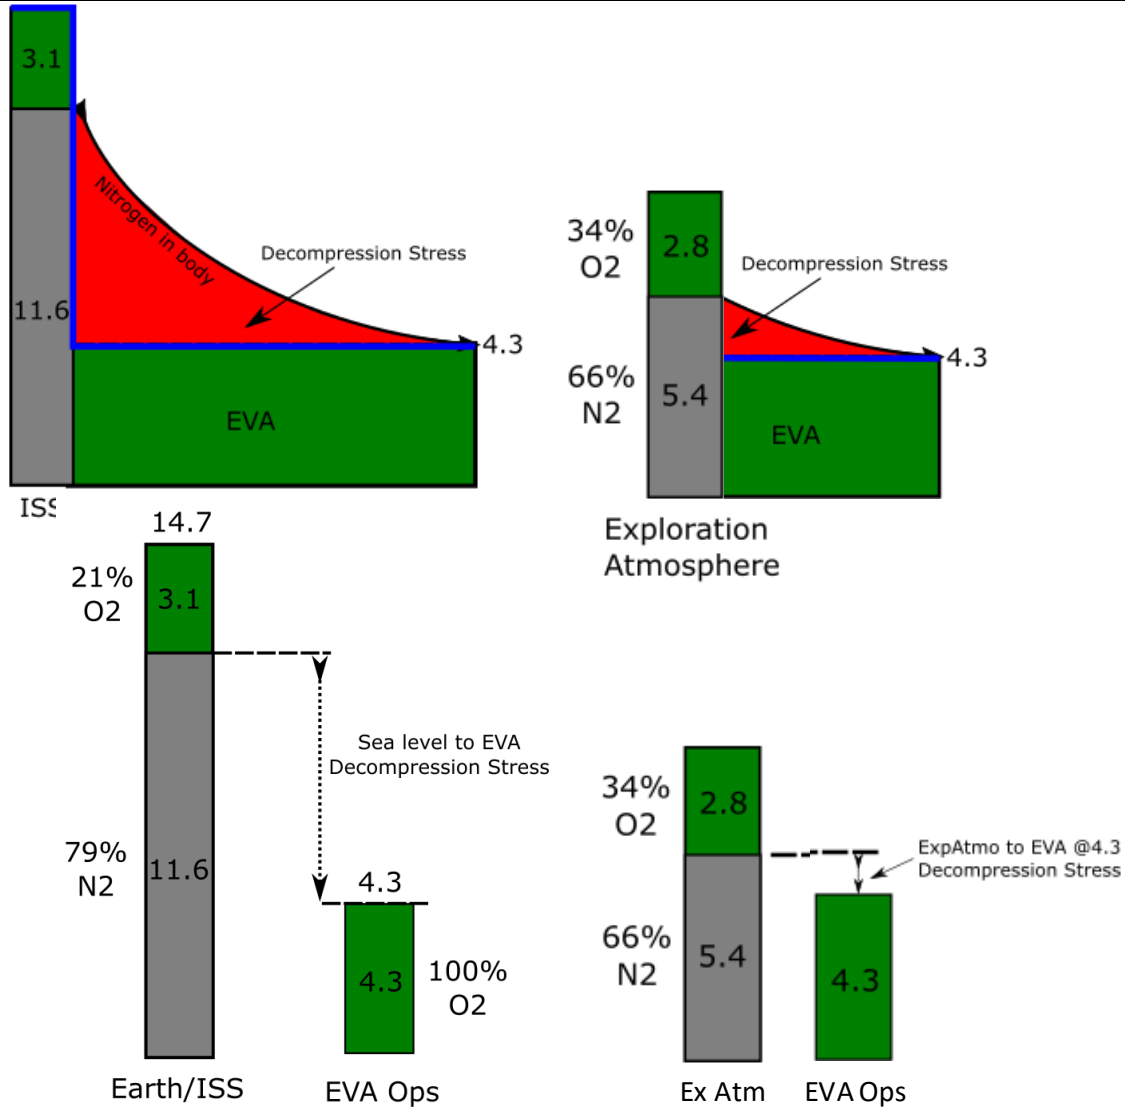

Contingency Planning: Medical

- **Must plan for, and train for contingencies well in advance**
 - Risk is a fact, not a concept and should be discussed *in advance*
 - Modeling is a tool NASA has traditionally used: (Integrated Medical Model (IMM) for ISS operations, and IMPACT for lunar operations, Tissue Bubble Dynamics Model for DCS)
 - Health Risk vs. Operational Risk
 - DCS will result in loss of mission objectives
 - 15% Type I per person per EVA ok from a health standpoint, but
 - Loss of EVA may not be acceptable from a mission standpoint
 - Lesson learned: modelling and discussing human health risk and operational risk as independent entities is critical to mission planning

Conditions for DCS (ISS vs. Planetary)

- ❖ Decrease in Pressure
- ❖ Change in Phase State
- ❖ Tissue pN₂ > Ambient Pressure

Programmatic Risk: DCS Mitigation

- To ↓ DCS risk efficiently:
- Engineering solutions such as a low N₂ atmosphere & variable pressure suits required
 - Requires cooperation & discourse between vendors
 - Proprietary info, competition, fixed price contracts, etc make such discussions a challenge
- Lesson Learned: Facilitating communication and cooperative controls between vendors is critical to effective solutions

Planetary Prebreathe Protocol Testing and Validation at NASA

What is “Exploration Atmospheres”?

- Study to validate lunar prebreathe (denitrogenation) options
- 12-day study with subjects “living” in a 3-story 20’ diameter chamber at about 15,000’ altitude
- 5 simulated EVAs, to determine a minimal acceptable duration
- Lesson Learned: a clear and reasonable written DCS disposition policy helps dispel the angst (and effects) of reporting

Creative Solutions: Suit as Chamber

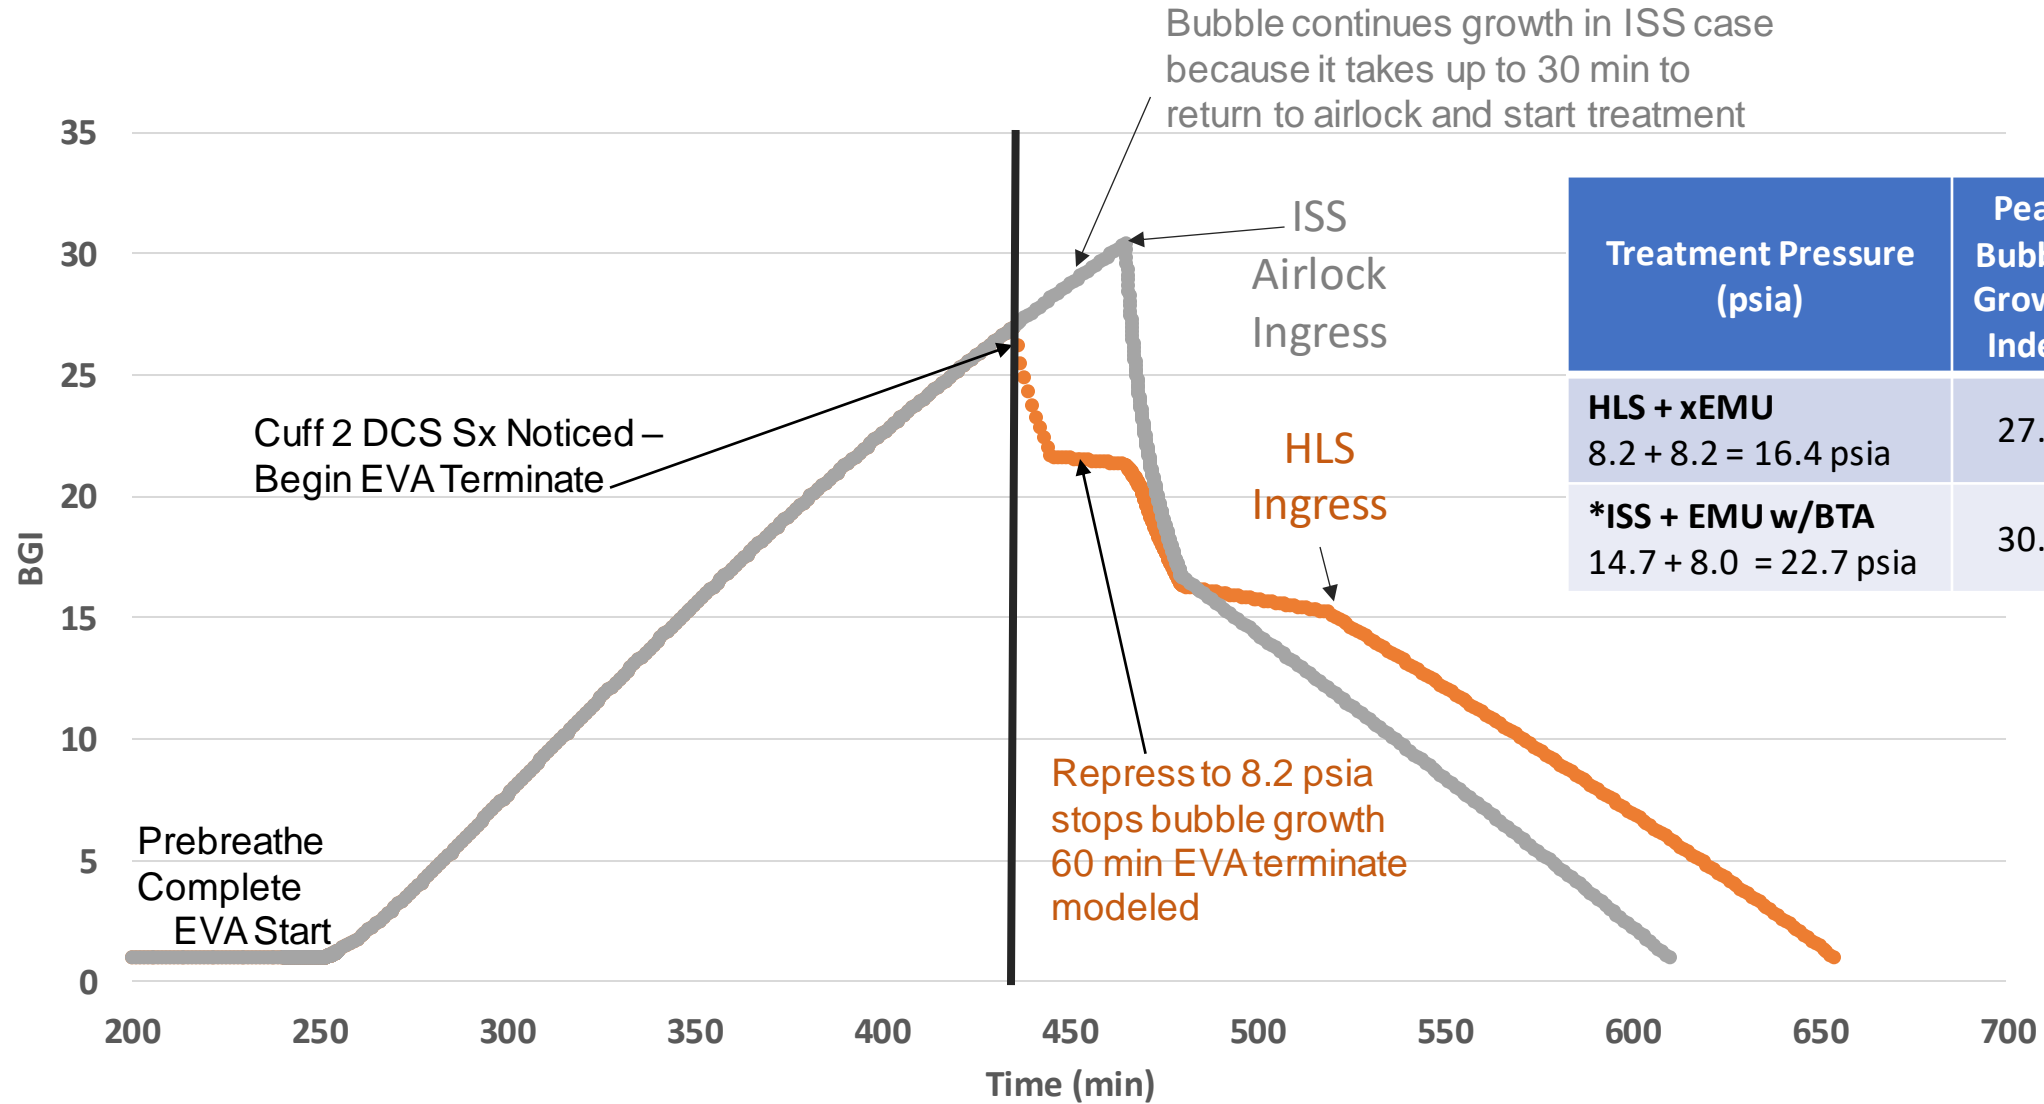

- **Treatment: chamber vs. suit**
 - Remain in suit
 - Recognition and exam (training *and* reporting)
 - Specialized neuro (to allow for in-suit diagnosis)
 - For lunar: potential comm delays require autonomy
- **Pressure relationships:**
 - Terrestrial (Diving DCS & Treatment):
 - Symptoms occur at 14.7 psi
 - Treatment pressure is 41 - 88 psi (60-165 fsw)
 - 2.8 - 6x *increase* in pressure
 - On Orbit (Lunar DCS & Treatment):
 - Symptoms occur at 4.3 psi
 - Treatment pressure is up to 18.4 psia
 - 4.3x *increase* in pressure
 - Unknown/untested efficacy but >14.7 psia / GLO

GLO: ground level oxygen

Bubble Dynamics* Comparison ISS vs Exploration Capabilities

● 8.2 HLS + 8.2 Suit

● ISS Reference

*Gernhardt M.L. Development and Evaluation of a Decompression Stress Index Based on Tissue Bubble Dynamics. Ph.D dissertation, University of Pennsylvania, UMI #9211935, 1991.

Conclusions

- **We can and will learn from each other**
 - Government/industry collaboration
- **Our missions may be different**
 - But people are the same
 - Risks and constraints are the same
- **We all need to work together and with industry to answer all the questions discussed today**

"How wonderful it is that nobody need wait a single moment before starting to improve the world." Anne Frank

Artemis Mission Impacts to Prevent DCS

*Assumes 6hr EVA @ 4.3 psia and approximately equal DCS risk level

Saturation Atmosphere	Planetary Prebreathe*
14.7 psi, 21% O ₂	6:30-7:00 ²
10.2 psi, 26.5% O ₂	3:00-3:30 ³
8.2 psi, 34% O₂	0:20 ^{4,5}
5.0 psi, 100% O ₂ (Apollo, Gemini)	0:00

Unvalidated estimates
(i.e., not yet available for flight)

Validated
2023

Artemis DCS Mitigation Process: Start with Engineering Solutions

- Low ppN₂ Atmosphere
 - 8.2 psia/34% O₂ for surface operations
 - Bounded by hypoxia and flammability (already optimized)
 - Flammable materials require Materials Usage Agreements (MUA)
- Variable Pressure Spacesuit
 - Capabilities required to enable Artemis missions
 - Government reference design has 4.3, 5.0, 6.2 and 8.2 psid
