The Role of Clinical Studies for Pets with Naturally
Occurring Tumors in Translational Cancer Research

June 8-9, 2015

Use and availability of canine cancer tissue banks
in translational research – the dog as a model for
accelerating gene discovery.

Matthew Breen PhD C.Biol. FSB

**Oscar J. Fletcher Distinguished Professor of Comparative Oncology Genetics
Dept. of Molecular Biomedical Sciences, College of Vet. Medicine, NC State University**

Center for Comparative Medicine and Translational Research, NCSU

Center for Human Health and the Environment, NCSU

Lineberger Comprehensive Cancer Center, UNC-Chapel Hill

One Medicine

"Between animal and human medicine there is no dividing line – nor should there be. The object is different but the experience obtained constitutes the basis of all medicine."

Rudolf Virchow (1821-1902)

How do we apply this to cancer research?

The traditional cancer model

SPONTANEOUS CANCERS

Canine cancer – breed predisposition

- 1. Cancer is a genetic disease**
- 2. Certain breeds of dog are highly affected by certain cancers (naturally occurring)**
- 3. Indicates that breeds of dog have an inherited predisposition to cancers**
- 4. Same environment as human**

POWERFUL OPPORTUNITY = identification of genetic factors in the dog will simultaneously offer major factors contributing to advancing cancer research in humans

One Medicine

~1.66 million diagnoses each year
(~500 cases/100,000 population)

~4.2 million diagnoses each year
(~5,300 dogs/100,000 population)

One Pathogenesis

Why do we need biobanks?

- **Research involving canine genetic or genomic information analyzed using biological specimens from well annotated patients is key to understanding complex diseases including cancer**
- **These data are key to advancing cancer detection, diagnosis, prognosis, intervention, treatment, and prevention.**
- **For maximum efficiency, establishment and sharing of resources is needed, comprising canine biological samples and information derived from their analysis.**

Requirements of effective biobanks

Key elements (SOPs)

SPECIMEN SELECTION AND STORAGE

Fit for purpose

High quality preparation, storage and retrieval

SPECIMEN ACCESS

Specimens and patient data accessible for research over time

SPECIMEN USE

Data sharing plan

CANINE COMPARATIVE

TISSUES WE CAN COLLECT FOR YOU

By utilizing our current tissue collection structure for our bank, we can tailor collections for the specific needs of your unique research. After submission of a brief on-line application, there will be follow up contact by the CCOGC to refine your request. We will assess the availability within our network; prepare Standard Operating Procedures and a budget. After your approval and a contract process, tissue collection will begin specifically designed for your research.

Quality control & quality assurance of canine biological specimens available through the Pfizer-CCOGC biospecimen repository for comparative oncology studies

Rachael Thomas^{1,2}, Mark Simpson³, Hiroyuki Mochizuki¹, Christina Williams¹, Kelsey Poorman¹, Katie Kennedy¹, Christina Mazcko⁴, Jaime F. Modiano^{5,6} and Matthew Breen^{1,2,7}

¹ Department of Molecular Biomedical Sciences, College of Veterinary Medicine, North Carolina State University, Raleigh, NC; ² Center for Comparative Medicine and Translational Research, North Carolina State University, Raleigh, NC; ³ Laboratory of Cancer Biology and Genetics & ⁴ Comparative Oncology Program, Center for Cancer Research, National Cancer Institute, Bethesda, MA; ⁵ Department of Veterinary Clinical Sciences, College of Veterinary Medicine, University of Minnesota, St. Paul, MN; ⁶ Masonic Cancer Center, University of Minnesota, Minneapolis, MN; ⁷ Cancer Genetics, Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill

Quality control and assurance parameters were assessed on a panel of biospecimens distributed randomly across the eight submitting institutions and the seven tumor histologies represented in the repository:

- 1) To perform a detailed review of the quality of the specimens as the primary reason for submission
- 2) To assess the quality of the specimens as the primary reason for submission

A total of 331 formalin-fixed and paraffin-embedded (FFPE) tumor specimens, representing a cross-section of all seven tumor histologies, was subjected to rigorous pathology re-review by a panel of board-certified veterinary pathologists at the NCI.

H&E-stained specimens were i) evaluated in context with the original histologic diagnosis assigned by the submitting veterinarian, and ii) assessed for tumor versus stromal contamination by routine histopathology, immunohistochemistry and quantitative morphometry¹.

The quality of each nucleic acid sample was then scored according to the following three parameters (maximum score for each parameter = 3). These scores were then summed to yield a global quality score for each specimen (maximum global quality score = 9).

Tumor DNA	25mg	200-280 value	Yield		
			High molecular weight	Minor degradation	Marked degradation
Tumor RNA	25mg	Yield	> 10ug	5 - 10ug	< 5ug
		200-280 value	> 2.0	1.0 - 2.0	< 1.0
		RIN	> 8	6 - 8	< 6
Blood DNA	0.2ml	Yield	> 3ug	1.5 - 3ug	< 1.5ug
		200-280 value	> 1.7	1.0 - 1.7	< 1.0
		Gen integrity	High molecular weight	Minor degradation	Marked degradation

This evaluation of the Pfizer-CCOGC Biospecimen Repository provides further data to reinforce the potential value of this sample collection for furthering advances in canine and comparative cancer studies.

Presented at AACR, The Translational Impact of Model Organisms on Cancer, Nov 2013

CANINE COMPARATIVE ONCOLOGY & GENOMICS CONSORTIUM

Pathology review – diagnosis verification

Tumor	Number of cases assessed	Number (%) of diagnoses corroborated
MCT	50	47 (94%)
HEM	50	32 (64%)
STS	49	44 (90%)
PUL	50	46 (92%)
OSA	42	42 (100%)
LSA	49	49 (100%)
MEL	41	35 (85%)
TOTAL	331	295 (89%)

Outcome of pathology re-review of 331 cases distributed across each of the seven tumor histologies.

CANINE COMPARATIVE ONCOLOGY & GENOMICS CONSORTIUM

Pathology review – tumor purity

Assessment of 132 cases according to the percentage of tumor versus stromal contamination contained within each specimen.

- Lymphomas consistently exhibited a high proportion of tumor
- Melanomas were more variable
- Osteosarcoma cases showed extensive variation.

CANINE COMPARATIVE ONCOLOGY & GENOMICS CONSORTIUM

Nucleic acid QC

188 cases, selected at random, from the biorepository to provide proportional representation of each tumor histology and submitting institution

The importance of pathologic review

**How are we using canine
well defined cancer patient
specimens to accelerate
cancer research for the
benefit of dogs and people?**

How are we approaching comparative oncology using the dog as a model?

Identification of inherited and somatic changes

molecular cytogenetics

gene expression

case-control GWAS

exome sequencing of tumor-normal pairs

WGS of tumor-normal pairs

Human and dog genome organization

46 chromosomes

22 autosomal pairs + sex chromosomes

78 chromosomes

38 autosomal pairs + sex chromosomes

pericentric
inversion

insertion/
duplication

reciprocal
translocation

Nature's biological filing cabinets become rearranged during cancers

interstitial
deletion

paracentric
inversion

..... some genes are missing, some genes are duplicated, and in certain cases some genes move to new locations where they do not get along well with their new neighbors

deletion

Now we have the reagents to ask some key questions

Q. Are there evolutionarily related chromosome aberrations that suggest an ancestral mechanism of pathogenetically significant events?

Rationale: look for well described human cytogenetic changes in canine cancers

One example of many

The Philadelphia chromosome - $\text{der}(22)\text{t}(9;22)(\text{q}34;\text{q}11)$

Comparative chromosome alignment

Dog chromosomes – predicted translocation

COLLEGE OF VETERINARY MEDICINE NORTH CAROLINA STATE UNIVERSITY

Q. Are there evolutionarily related chromosome aberrations which suggest an ancestral mechanism of pathogenetically significant events ?

A. YES but what could this mean for human and dog patients?

VETERINARY PERSPECTIVE = same pathogenetic mechanism = same treatments ?

MEDICAL PERSPECTIVE = differential organization of the dog genome may narrow key regions of the genome associated with cancers

Q. CAN WE USE THE GENOME OF THE DOG TO IDENTIFY CANCER GENES THUS FAR 'HIDDEN' IN THE HUMAN GENOME

Contrasting architecture of the dog and human genomes offers tremendous potential to refine regions of significance

HUMAN $2n = 46$
 bi-armed autosomes
 range from 247Mb - 47Mb

DOMESTIC DOG $2n = 78$
 single-armed autosomes
 range from 125Mb - 26Mb

THE HUMAN KARYOTYPE VISUALIZED AS A DOG KARYOTYPE

Comparative genomic map of human 22 and the domestic dog

Cytogenetics of meningiomas

Among the first solid tumors recognized as having cytogenetic alterations (Mark *et al.* 1972)

- A hallmark genomic imbalance of meningiomas is either the partial (del(22)(q12)) or **total deletion of chromosome 22**
= up to a 50Mb deletion with over 500 genes

- Loss of chromosome 22 more often occurs in low grade meningiomas (implies key early event?)
- Deletions frequently involve the region HSA 22q12 (NF2)

Canine TCC/UC (bladder cancer)

SYMPTOMS of urothelial cancer in the dog are shared with variety of other urinary tract conditions
e.g. bladder infection/inflammation, bladder stones

APPROACHES to diagnosis currently:

cytology - can be misleading, relies on abnormal cells which may be shed due to other conditions

imaging - tumor, inflammation ?

biopsy- only way to conclusively diagnose and obtained by traumatic catheterization or cystoscopy, both of which carry risk of seeding = ***reluctance to biopsy***

Diagnostic challenge

(>2.5M cases of UTI p.a)

Demand for a FC-urine diagnostic for TCC

oaCGH profiling of canine TCC – cohort analysis

Whole chromosome aneuploidy of 13/19/36 in canine TCC is unidirectional and highly recurrent
