Areas of Evidence Analysis for Genomics

Gene-Disease Association Evidence

>4300 gene-disease associations but many do not have sufficient data to support a definitive relationship

Informs content for tests and genomic interpretations

Variant Pathogenicity Evidence

>50 million variants have been found in the human genome and many are unique to an individual

Misinterpretation can impact clinical care and study outcomes

Evidence for an Outcome

- Phenotype or prognosis prediction
- Therapeutic response prediction
- Adverse event avoidance

TRANSLATIONAL GENETICS — OPINION

Disease-targeted sequencing: a cornerstone in the clinic

Heidi L. Rehm

Abstract | With the declining cost of sequencing and the ongoing discovery of disease genes, it is now possible to examine hundreds of genes in a single disease-targeted test. Although exome- and genome-sequencing approaches are beginning to compete, disease-targeted testing retains certain advantages and still holds a firm place in the diagnostic evaluation. Here I examine the current sta… the benefits and chall….

ACMG PRACTICE GUIDELINES | Genetics inMedicine

ACMG clinical laboratory standards for next-generation sequencing

Heidi L. Rehm, PhD[1,2], Sherri J. Bale, PhD[3], Pinar Bayrak-Toydemir, MD, PhD[4], Jonathan S. Berg, MD[5], Kerry K. Brown, PhD[6], Joshua L. Deignan, PhD[7], Michael J. Friez, PhD[8], Birgit H. Funke, PhD[1,2], Madhuri R. Hegde, PhD[9] and Elaine Lyon, PhD[4]; for the Working Group of the American College of Medical Genetics and Genomics Laboratory Quality Assurance Committee

Disclaimer: These American College of Medical Genetics and Genomics Standards and Guidelines are developed primarily as an educational resource for clinical laboratory geneticists to help them provide quality clinical laboratory genetic services. Adherence to these standards and guidelines is voluntary and does not necessarily assure a successful medical outcome. These Standards and Guidelines should not be considered inclusive of all proper procedures and tests or exclusive of other procedures and tests that are reasonably directed to obtaining the same results. In determining the propriety of any specific procedure or test, the clinical laboratory geneticist should apply his or her own professional judgment to the specific circumstances presented by the individual patient or specimen. Clinical laboratory geneticists are encouraged to document in the patient's record the rationale for the use of a particular procedure or test, whether or not it is in conformance with these Standards and Guidelines. They also are advised to take notice of the date any particular guideline was adopted and to consider other relevant medical and scientific information that becomes available after that date. It also would be prudent to consider whether intellectual property interests may restrict the performance of certain tests and other procedures.

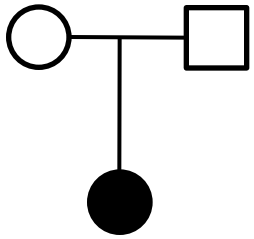
Clinical Exome/Genome Sequencing: A New Challenge in Evidence Generation



Distal Arthrogryposis Type 5

- Disease is known to be AD and to occur *de novo*
- No known genes for DA5

Clinical features:

Skeletal	Spine stiffness, Hunched anteverted shoulders, Pectus excavatum, Limited forearm rotation and wrist extension, Bilateral club feet, Congenital finger contractures, Long fingers, Absent phalangeal creases, Poorly formed palmar creases, Camptodactyly, Dimples over large joints
Muscle	Decreased muscle mass (especially in lower limbs), Firm muscles
Face	Triangular face, Decreased facial expression
Ears	Prominent ears
Eyes	Ophthalmoplegia, Deep-set eyes, Epicanthal folds, Ptosis, Duane anomaly, Keratoglobus, Keratoconus, Macular retinal folds, Strabismus, Astigmatism, Abnormal electroretinogram, Abnormal retinal pigmentation

Case from
Michael Murray, MD

WGS Case: Distal Arthrogryposis Type 5

Two de novo mutations in exonic sequence:

ACSM4 – acyl-CoA synthetase medium-chain family member 4
5 nonsense variants identified in ESP; 1 with 6.4% MAF;

PIEZO2: mechanosensitive ion channel

Shamil Sunyeav

Great candidate, but how to we prove causality for a novel gene-disease association?

Then came serendipity……

Second DA5 family with *PIEZO2* mutation was found

Gain-of-function mutations in the mechanically activated ion channel PIEZO2 cause Distal Arthrogryposis Type 5

GENERAL GENOME REPORT

RESULT SUMMARY

Sequencing of this individual's genome was performed and covered 95.8% of all positions at 8X coverage or higher, resulting in over 5.2 million variants compared to reference genome. These data were analyzed to identify previously reported variants of potential clinical relevance as well as novel variants that could reasonably be assumed to cause disease (see methodology below). All results are summarized on page 1 with further details on subsequent pages.

A. MONOGENIC DISEASE RISK: 1 VARIANT IDENTIFIED

This test identified 1 genetic variant that may be responsible for existing disease or the development of disease in this individual's lifetime.

Disease (Inheritance)	Phenotype	Gene (Variant)	Classification
A1. X-linked recessive chondrodysplasia punctata (X-linked)	Abnormal bone and cartilage development	ARSE (c.410G>C p.Gly137Ala)	Uncertain Significance: Favor pathogenic

B. CARRIER RISK: 2 VARIANTS IDENTIFIED

This test identified carrier status for 2 autosomal recessive disorders.

Disease (Inheritance)	Phenotype	Gene (Variant)	Classification	Carrier Phenotype*
B1. Methylmalonic aciduria and homocystinuria,cblC type (Autosomal recessive)	Disorder of cobalamin metabolism	MMACHC (c.271_272insA p.Arg91LysfsX14)	Pathogenic	None Reported
B2. Leber congenital amaurosis (Autosomal recessive)	Retinal dystrophy and blindness	SPATA7 (c.94+2T>C)	Likely Pathogenic	None Reported

As a carrier for recessive genetic variants, this individual is at higher risk for having a child with one or more of these highly penetrant disorders. To determine the risk for this individual's future children to be affected, the partner of this individual would also need to be tested for these variants. Other biologically related family members may also be carriers of these variants. *Carriers for some recessive disorders may be at risk for certain phenotypes. Please see variant descriptions for more information.

C. PHARMACOGENOMIC ASSOCIATIONS

This test identified the following pharmacogenomic associations. Additional pharmacogenomic results may be requested, but will require additional molecular confirmation prior to disclosure.

Drug	Risk and Dosing Information
C1. Warfarin	Decreased dose requirement
C2. Clopidogrel	Typical response to clopidogrel
C3. Digoxin	Intermediate metabolism and serum concentration of digoxin
C4. Metformin	Intermediate glycemic response to metformin
C5. Simvastatin	Typical risk of simvastatin-related myopathy

D. BLOOD GROUPS

This test identified the ABO Rh blood type as B Positive. Additional blood group information is available at the end of the report.

It should be noted that the disease risk section of this report is limited only to variants with strong evidence for causing highly penetrant disease, or contributing to highly penetrant disease in a recessive manner. Not all variants identified have been analyzed, and not all regions of the genome have been adequately sequenced. These results should be interpreted in the context of the patient's medical evaluation, family history, and racial/ethnic background. Please note that variant classification and/or interpretation may change over time if more information becomes available. For questions about this report, please contact the Genome Resource Center at GRC@partners.org.

Monogenic Disease and Carrier Risk

Detailed Variant Information

Disease (Inheritance)	Gene (Transcript)	Variant (Classification)	Variant Frequency	Disease Prevalence	References
A1. X-linked recessive chondrodysplasia punctata (X-linked)	ARSE (NM_000047.2)	c.410G>C p.Gly137Ala hemizygous (Uncertain Significance)	1/6728 European American	1:500,000	Sheffield 1998, Nino 2008, Franco 1995, Matos-Miranda 2013

VARIANT INTERPRETATION: The Gly137Ala variant in ARSE has been previously identified in 2 males with chondrodysplasia punctata; however, this variant was also identified in one unaffected male family member (Sheffield 1998, Nino 2008). Variants in a paralogous gene (ARSB) at the same position have also been identified in an individual with Maroteux-Lamy syndrome, which also features skeletal abnormalities (Franco 1995). Functional studies indicate that the Gly137Ala variant leads to reduced ARSE activity (Matos-Miranda 2013). In summary, although some data support a disease-causing role, there is currently insufficient evidence for pathogenicity leading to a current classification of uncertain significance.

DISEASE INFORMATION: X-linked chondrodysplasia punctata 1 (CDPX1), a congenital disorder of bone and cartilage development, is caused by a deficiency of the Golgi enzyme arylsulfatase E (ARSE). It is characterized by chondrodysplasia punctata (stippled epiphyses), brachytelephalangy (shortening of the distal phalanges), and nasomaxillary hypoplasia. Although most affected males have minimal morbidity and skeletal findings that improve by adulthood, some have significant medical problems including respiratory compromise, cervical spine stenosis and instability, mixed conductive and sensorineural hearing loss, and abnormal cognitive development. From GeneReviews abstract: http://www.ncbi.nlm.nih.gov/books/NBK1544/

FAMILIAL RISK: X-Linked chondrodysplasia punctata is inherited in an X-linked recessive manner, with primarily males being affected. Each child is at a 50% (or 1 in 2) chance of inheriting the variant from a carrier female, while all daughters will inherit the variant from an affected male.

“Evidence Generation” session at Global Leaders in Genomic Medicine Meeting

Priorities areas of focus to enable genomic medicine implementation

1. Need definitions of evidence (gene, variant, test, treatment)
2. Develop standards for a test (method, content, interpretation, risk prediction)
3. Catalog evidence generating projects – IGNITE?
    - Define status of projects to decide which to implement elsewhere, which could benefit from larger datasets and which should not be prioritized elsewhere due to poor evidence for effect
4. Encourage adoption of genomic medicine applications with existing evidence
    - Identify areas of economic benefit
    - Engage physicians in identifying areas of opportunity for genomic implementation
    - Stimulate development of society practice guidelines
    - Intersociety coordinating committee – competencies in residency training
5. Discuss areas of overlap with activities of other organizations
6. Identify countries/systems willing to enable access to patient data
    - Share evidence generated in those systems
7. Need systems to capture evidence - Facilitate a federated network and standardized APIs to share data – GA4GH?

Returning Results from Large Panels and Genomic Tests

Key Questions:

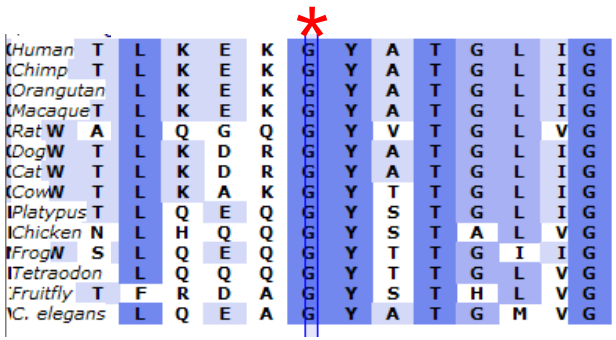
Is there strong evidence for the gene's role in disease?

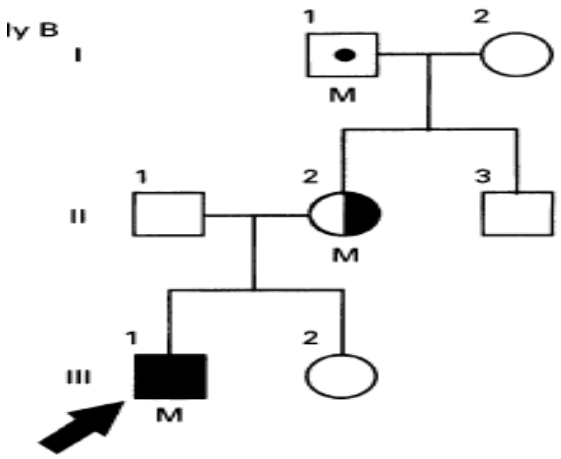
Is there strong evidence for variant pathogenicity?

Does this result explain the indication for testing?
OR
Should I return the result as an Incidental Finding?

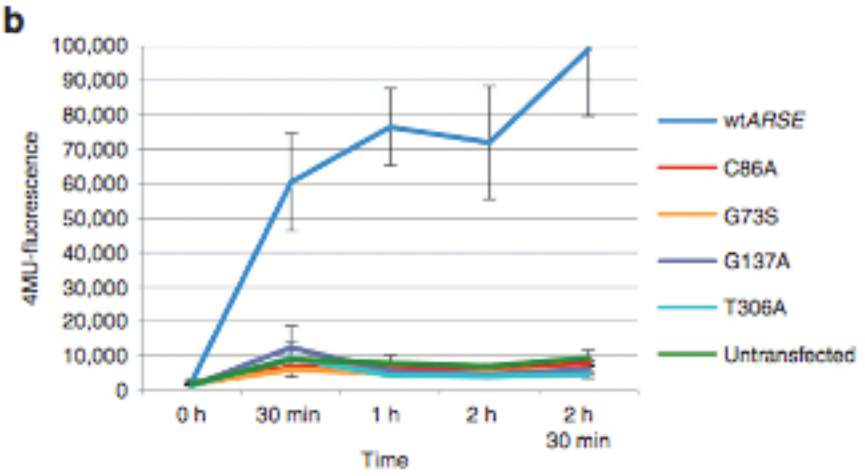
ARSE p.Gly137Ala – Reported Pathogenic

- Strong evidence for ARSE role in XLR chondrodysplasia punctata 1
- Variants identified in 2 males with CDPX1, one severe, one mild
- 1/6728 female EA ESP; 1 asymptomatic male
- Pathogenic by PolyPhen, SIFT, AlignGVGD
- Functional studies show reduced ARSE activity after expressing the mutant *ARSE* cDNA in mammalian COS1 cells and measuring ARSE activity using 4MU sulfate





Sheffield, et al. J Med Genet 1998



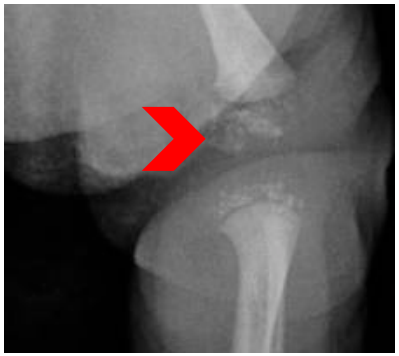
Matose-Miranda, et al. Genet Med 2013

MedSeq Case – Adult Male

ARSE c.410G>C (p.Gly137Ala) Hemizygous

Pathogenic ARSE variants à XLR chrondodysplasia punctata 1 (CDPX1)

- Most males have mild disease that improves by adulthood
- Variable intrafamilial disease expression



Epiphyseal stippling (100%)
Brachytelephalangy (68%)
Nasomaxillary hypoplasia (58%)

Minimal morbidity

Severe morbidity
Respiratory disease (32%)
Cervical spine stenosis (19%)
Hearing loss (26%)
Cognitive delay (16%)
Eye abnls (16%)
Cardiac abnls (13%)
Infant demise (13%)

TOR1A: c.726del (p.Ser243fs)

- Novel variant, Not present in EVS or 1000Genomes
- Predicted loss of 116 amino acids (third of protein); predicted NMD
- No other truncating mutations in ESP cohorts
- No other splice forms of gene described

TOR1A strongly associated with Early-Onset Primary Dystonia (DYT1)

- Typically presents in childhood or adolescence, range 4-64 years
- Dystonic muscle contractions causing posturing of a foot, leg, or arm are most common
- Autosomal dominant with incomplete penetrance (30%) and variable expressivity
- Disease prevalence: AJ population 1/3000 – 1/9000
  Europe: 1/200,000-330,000
- Clinical testing available
- Actionability: Oral medications and surgical intervention to prevent contractures of the joints and deformities of the spine

TOR1A: c.726del (p.Ser243fs)

- Common mutation: c.907_909delGAG

- Mechanism of variant pathogenicity not well established
  - Gain-of function?
  - Loss-of-function with haploinsufficiency?

- Tor1A knockdown mice expressing reduced levels of torsin A exhibit deficits in motor control and alterations similar to those displayed by KI heterozygous mice

<u>Other variants:</u>

- 3 other putative pathogenic variants, all non-truncating, all insufficient evidence
  - Phe205Ile, Arg288Gln, Phe323_Tyr328del
- 1 loss of function variant found in an anonymous blood donor specimen:
  - Arg312fs
